

## FM-pipeline

FineMapping analysis using GWAS summary statistics

### INTRODUCTION

This is a pipeline for finemapping using GWAS summary statistics, implemented in Bash as a series of steps to furnish an incremental analysis. As depicted in the diagram below

### ***LocusZoom plot showing Regional association for chr1:39114617-39614617***

where our lead SNP rs4970634 is in LD with many others, the procedure attempts to identify causal variants from region(s) showing significant SNP-trait association.

The process involves the following steps, 1. Extraction of effect (beta)/z statistics from GWAS summary statistics (.sumstats), 2. Extraction of correlation from the reference panel among overlapped SNPs from 1 and the reference panel containing individual level data. 3. Information from 1 and 2 above is then used as input for finemapping.

The measure of evidence is typically (log10) Bayes factor (BF) and associate SNP probability in the causal set.

Information on whole-genome analysis, which could be used to set up the regions, are described at the [wiki page](#). Clumping using PLINK is also included analogous to those used in depict (e.g. description in [PW-pipeline](#)).

## INSTALLATION

Software options included in this pipeline are listed in the table below.

Option	Name	Function	Input	Output	Reference
CAVIAR	CAVIAR	finemapping	z, correlation matrix	causal sets and probabilities	Hormozdiari, et al. (2014)
CAVIARBF	CAVIARBF	finemapping	z, correlation matrix	BF and probabilities for all configurations	Chen, et al. (2015)
GCTA	GCTA	joint/conditional analysis	.sumstats, reference data	association results	Yang, et al. (2012)
FM_summary	FM- summary	finemapping	.sumstats	posterior probability & credible set	Huang, et al. (2017)
JAM	JAM	finemapping	beta, individual reference data	Bayes Factor of being causal	Newcombe, et al. (2016)
LocusZoom	LocusZoom	regional plot	.sumstats	.pdf/.png plots	Pruim, et al. (2010)
fgwas	fgwas	functional GWAS	.sumstats	functional significance	Pickrell (2014)
finemap	finemap	finemapping	z, correlation matrix	causal SNPs and configuration	Benner, et al. (2016)

so they range from regional association plots via LocusZoom, joint/conditional analysis via GCTA, functional annotation via fgwas to dedicated finemapping software including CAVIAR, CAVIARBF, an adapted version of FM-summary, R2BGLiMS/JAM and finemap. One can optionally use a subset of these for a particular analysis by specifying relevant flags from the pipeline's settings.

On many occasions, the pipeline takes advantage of the [GNU parallel](#). Besides (sub)set of software listed in the table above, the pipeline requires [qctool](#) 2.0, [PLINK](#) 1.9, and the companion program LDstore from finemap's website need to be installed. To facilitate handling of graphics, e.g., importing them into Excel, pdftopng from [XpdfReader](#) is used. We use [Stata](#) and Sun grid engine (sge) for some of the data preparation, which would become handy when available.

The pipeline itself can be installed in the usual way,

```
git clone https://github.com/jinghuazhao/FM-pipeline
```

## USAGE

An `fmp.ini` needs to be present at the working directory,

The pipeline is then called with

```
bash fmp.sh <input>
```

## Inputs

### — GWAS summary statistics —

The input will be GWAS summary statistics described at <https://github.com/jinghuazhao/SUMSTATS>, in line with joint/conditional analysis by GCTA involving chromosomal positions.

### — Reference panel —

The pipeline uses a reference panel in a `.gen.gz` format, taking into account directions of effect in both the GWAS summary statistics and the reference panel. Its development will facilitate summary statistics from a variety of consortia as with reference panels such as the HRC and 1000Genomes.

A `.gen.gz` file is required for each region, named such that `chr{chr}_{start}_{end}.gen.gz`, together with a sample file. For our own data, [st.do](#) is written to generate such files from their whole chromosome counterpart using `SNPinfo.dta.gz` which has the following information,

chr	rsid	RSnum	pos	FreqA2	info	type	A1	A2
1	1:54591_A_G	rs561234294	54591	.0000783	.33544	0	A	G
1	1:55351_T_A	rs531766459	55351	.0003424	.5033	0	T	A
...	...	...	...	...	...	...	...	...

We may also work on a text version for instance `SNPinfo.txt`.

### — The lead SNPs —

The setup is in line with summary statistics from consortia where only `RSid` are given for the fact that their chromosomal position may be changed over different builds. An auxiliary file called `st.bed` contains `chr`, `start`, `end`, `rsid`, `pos`, `r` corresponding to the lead SNPs specified and `r` is a sequence number of region.

## Outputs

The output will involve counterpart(s) from individual software, i.e., `.set/post`, `caviarbf`, `.snp/.config`, `jam/.top`

Software	Output type	Description
CAVIAR	<code>.set/.post</code>	causal set and probabilities in the causal set/posterior

		probabilities
CAVIARBF	.caviarbf	causal configurations and their BF's
FM-summary	.txt	additional information to the GWAS summary statistics
GCTA	.jma.cojo	joint/conditional analysis results
JAM	.jam/.top/.cs	posterior summary table, top models containing selected SNPs and credible sets
finemap	.snp/.config	top SNPs with largest log10(BF) and top configurations as with their log10(BF)

It is helpful to examine directions of effects together with their correlation which is now embedded when finemap is involved.

## EXAMPLE

Files `bmi.tsv.gz` and `97.snps` are described in <https://github.com/jinghuazhao/SUMSTATS>.

### — 1000Genomes panel using approximately indepdent LD blocks —

This is available as [FUSION LD reference panel](#), with [1KG.sh](#) to generate `SNPinfo.dta.gz` and [st.do](#) to generate the script [Extract.sh](#) for the required data.

We then proceed with

```
awk '{gsub(/chr/, "", $0); if(NR==1) {print "chr", "start", "end", "region"} else
print $1, $2, $3, $4}' 1KG/EUR.bed > st.bed
gunzip bmi.tsv.gz > BMI_1KG
# modify fmp.ini to use the 1KG panel
fmp.sh BMI_1KG
```

and the results will be in `BMI_1KG.out`.

### — HRC panel —

Assuming an HRC panel is ready, file `97.snps` is used to build `st.bed` and the analysis proceeds as follows,

```
# st.bed
(
  echo "chr start end rsid pos r"
  grep -w -f 97.snps snp150.txt | \
  sort -k1,1n -k2,2n | \
  awk -vflanking=250000 '{print $1, $2-flanking, $2+flanking, $3, $2, NR}'
) > st.bed
gunzip -c bmi.tsv.gz > BMI_HRC
# modify fmp.ini to use the HRC panel
# export GEN_Location=/scratch/tempjhz22/LDcalc/HRC
fmp.sh BMI_HRC
```

and the results will be in BMI\_HRC.out.

## ADDITIONAL TOPICS

The [wiki page](#) has the following information,

- [Whole-genome conditional/joint analysis](#)
- [Whole genome analysis using approximately independent LD blocks.](#)

## RELATED LINK

Credible sets are often described, see <https://github.com/statgen/gwas-credible-sets>

## ACKNOWLEDGEMENTS

The work was motivated by finemapping analysis at the MRC Epidemiology Unit and inputs from authors of GCTA, finemap, JAM, FM-summary as with participants in the Physalia course Practical GWAS Using Linux and R are greatly appreciated. In particular, the [utility program in Stata](#) was adapted from [p0.do](#) (which is still used when LD\_MAGIC is enabled) originally written by Dr Jian'an Luan and [computeCorrelationsImpute2forFINEMAP.r](#) by Ji Chen from the MAGIC consortium who also provides code calculating the credible set based on finemap configurations. Earlier version of the pipeline also used [GTOOL](#).
